

Working Prototype Known Problems Report

Medicine Tracker

Pill Slugs

11/30/2021

Functions not working correctly:

1. Web Browser - Within every state of the web application (except for the login page) if you click on the refresh button, the backend will disconnect and will no longer supply user information stored in the backend. I think to fix this bug we would have to have authentication throughout each state of our web application.
2. Medicine.js - Within the MedForm function, for the putMedicine function when we try to edit the medicine information from the medicine list, the parameter input doesn't update quick enough so the Medicine gets updated to the empty input and therefore the medicine information changes to blanks if every field isn't changed.
3. Using Google ID as the ID for users, because googles google Ids will change eventually.
4. Medicine.js - Within the MedForm function, for the putMedicine function when we try to add a new medicine, if the imputed name length is too long, it will overlap with the delete, edit, and dropdown buttons. To fix this, make the placements of these buttons dynamic depending on name length.
5. DailyList.js- When the list becomes long from adding many medications, two scroll bars appear and in order to see the bottom, both must be scrolled. To fix

this, only let the dailylist be able to scroll while not allowing the home page to scroll.

6. MedicineList.js - Unable to delete medicine if the medicine count is 1. To fix this bug, we tried to print out the medicine list before and after delete but we believe that the component didn't update fast enough and therefore did not capture that the database already deleted the medicine.
